

Vertical and Conglomerate Mergers

Introduction

- General Electric and Honeywell proposed to merge in 2000
 - GE supplies jet engines for commercial aircraft
 - Honeywell produced various electrical and other control systems for jet aircraft
- Deal was approved in the US
- But was blocked by the EU Competition Directorate
 - this was a merger of *complementary* firms
 - it is “like” a vertical merger
 - so can potentially remove inefficiencies in pricing
 - *benefiting the merged firms and consumers*
 - so why block the merger?

Introduction 2

- Vertical mergers can be detrimental
 - if they facilitate market foreclosure by the merged firms
 - *refuse to supply non-merged rivals*
- But they can also be beneficial
 - if they remove market inefficiencies
- Regulators need to look for the balance these two forces in considering any proposed merger

Complementary Mergers

- Consider first a merger between firms that supply *complementary products*
- A simple example:
 - final production requires two inputs in fixed proportions
 - one unit of each input is needed to make one unit of output
 - input producers are monopolists
 - final product producer is a monopolist
 - demand for the final product is $P = 140 - Q$
 - marginal costs of upstream producers and final producer (other than for the two inputs) normalized to zero.
- What is the effect of merger between the two upstream producers?

Complementary mergers 2

Complementary producers

- ◆ Consider the profit of the final producer: this is

$$\pi^f = (P - v_1 - v_2)Q = (140 - v_1 - v_2 - Q)Q$$

- ◆ Maximize this with respect to Q

$$\partial \pi^f / \partial Q = 140 - (v_1 + v_2) - 2Q = 0$$

Solve this for Q

$$\therefore Q = 70 - (v_1 + v_2)/2$$

- ◆ This gives us the demand for each input

$$Q_1 = Q_2 = 70 - (v_1 + v_2)/2$$

- ◆ So the profit of supplier 1 is then:

$$\pi^1 = v_1 Q_1 = v_1 (70 - v_1/2 - v_2/2)$$

- ◆ Maximize this with respect to v_1

The price charged by each supplier is a function of the other supplier's price

Elementary producer

We need to solve these two pricing equations

Solve this for v_1

- ◆ Maximize this with respect to v_1

$$\partial \pi^1 / \partial v_1 = 70 - v_1 - v_2/2 = 0$$

$$v_1 = 70 - v_2/2$$

- ◆ We can do exactly the same for v_2

$$v_2 = 70 - v_1/2$$

$$v_1 = 70 - (70 - v_1/2)/2 = 35 + v_1/4$$

$$\text{so } 3v_1/4 = 35, \text{ i.e., } v_1 = \$46.67$$

$$\text{and } v_2 = \$46.67$$

Complementary products 3

- ◆ Recall that $Q = Q_1 = Q_2 = 70 - (v_1 + v_2)/2$
so $Q = Q_1 = Q_2 = 23.33$ units
- ◆ The final product price is $P = 140 - Q = \$116.67$
- ◆ Profits of the three firms are then:
supplier 1 and supplier 2: $\pi_1 = \pi_2 = 46.67 \times 23.33 = \$1,088.81$
final producer: $\pi^f = (116.67 - 46.67 - 46.67) \times 23.33 = \544.29

Complementary Products 4

*Now suppose that the
two suppliers merge*

Supplier 1

23.33 units @
\$46.67 each

Supplier 2

23.33 units @
\$46.67 each

Final Producer

23.33 units @ \$116.67 each

Consumers

Complementary mergers 5

Complementary mergers 6

- ◆ Consider the profit of the final producer: this is

$$\pi^f = (P - v)Q = (140 - v - Q)Q$$

- ◆ Maximize this with respect to Q

$$\partial \pi^f / \partial Q = 140 - v - 2Q = 0$$

Solve this for
Q

$$\therefore Q = 70 - v/2$$

- ◆ This gives us the demand for each input

$$Q_1 = Q_2 = Q_m = 70 - v/2$$

- ◆ So the profit of the merged supplier is:

$$\pi^m = vQ_m = v(70 - v/2)$$

- ◆ Maximize this with respect to v

Complementarity

$$\pi^m = vQ_m = v(70 - v/2)$$

- ◆ Differentiate with respect to v

$$\partial\pi^m/\partial v = 70 - v = 0$$

$$\text{so } v = \$70$$

- ◆ Recall that $Q_m = Q = 70 - v/2$ so $Q_m = Q = 35$ units

- ◆ This gives the final product price $P = 140 - Q = \$105$

- ◆ What about profits? For the merged

$$\pi^m = vQ_m = 70 \times 35 = \$2,480$$

- ◆ For the final producer:

$$\pi^f = (105 - 70) \times 35 = \$1,225$$

This is the cost of the combined input: the merged firm's costs to the final producer

The merger has reduced the final product price: consumers gain

This is greater than the combined pre-merger profit

This is greater than the pre-merger profit

Complementary mergers 8

- A merger of complementary producers has
 - increased profits of the merged firms
 - increased profit of the final producer
 - reduced the price charged to consumers

Everybody gains from this merger: a Pareto improvement! Why?

- This merger corrects a market failure
 - prior to the merger the upstream suppliers do not take full account of their interdependence
 - cut in price by one of them reduces downstream costs, increases downstream output and benefits the other upstream firm
 - but this is an **externality** and so is ignored
- Merger internalizes the externality

Vertical Mergers

- The same result arises when we consider *vertical mergers*: mergers of upstream and downstream firms
- If the merging firms have market power
 - lack of co-ordination in their independent decisions
 - ***double marginalization***
 - merger can lead to a general improvement
- Illustrate with a simple model
 - one upstream and one downstream monopolist
 - ***manufacturer and retailer***
 - upstream firm has marginal costs c
 - sells product to the retailer at price r per unit
 - no other retail costs: one unit of input gives one unit of output
 - retail demand is $P = A - BQ$

Vertical merger 2

Vertical merger 3

- Consider the retailer's decision
 - identify profit-maximizing output
 - set the profit maximizing price

- ♦ marginal revenue downstream is $MR = A - 2BQ$
- ♦ retail marginal cost is r
- ♦ equate $MC = MR$ to give the quantity $Q = (A - r)/2B$
- ♦ identify the price from the demand curve: $P = A - BQ = (A + r)/2$
- ♦ profit to the retailer is $(P - r)Q$ which is $\pi^D = (A - r)^2/4B$
- ♦ profit to the manufacturer is $(r - c)Q$ which is $\pi^M = (r - c)(A - r)/2B$

Vertical merger 4

- ♦ suppose the manufacturer sets a different price r_1
- ♦ then the downstream firm's output choice changes to the output $Q_1 = (A - r_1)/2B$
- ♦ and so on for other input prices
- ♦ demand for the manufacturer's output is just the downstream marginal revenue curve

Vertical merger 5

- ♦ the manufacturer's marginal cost is c
- ♦ upstream demand is $Q = (A - r)/2B$ which is $r = A - 2BQ$
- ♦ upstream marginal revenue is, therefore, $MR_u = A - 4BQ$
- ♦ equate $MR_u = MC$: $A - 4BQ = c$
- ♦ so $Q^* = (A-c)/4B$ the input price is $(A+c)/2$
- ♦ while the consumer price is $(3A+c)/4$
- ♦ the manufacturer's profit is $(A-c)^2/8B$
- ♦ the retailer's profit is $(A-c)^2/16B$

Vertical merger 6

- Now suppose that the retailer and manufacturer merge
 - manufacturer takes over the retail outlet
 - retailer is now a downstream division of an integrated firm
 - the integrated firm aims to maximize total profit
 - Suppose the upstream division sets an internal (transfer) price of r for its product
 - Suppose that consumer demand is $P = P(Q)$
 - Total profit is:
 - *upstream division:* $(r - c)Q$
 - *downstream division:* $(P(Q) - r)Q$
 - *aggregate profit:* $(P(Q) - c)Q$
- Back to the example

The internal transfer price nets out of the profit calculations

Vertical merger 7

This merger has benefited the two firms

merger has benefited consumers

Integrated demand is $P(Q) = A - BQ$
 Total revenue is $MR = A - 2BQ$

Variable cost is c

so the profit-maximizing output requires that $A - 2BQ = c$

♦ so $Q^* = (A - c)/2B$

♦ so the retail price is $P = (A + c)/2$

♦ aggregate profit of the integrated firm is $(A - c)^2/4B$

Vertical merger 8

- Integration increases profits *and* consumer surplus
- Why?
 - the firms have some degree of market power
 - so they price above marginal cost
 - so integration corrects a market failure: double marginalization
- What if manufacture were competitive?
 - retailer plays off manufacturers against each other
 - so obtains input at marginal cost
 - gets the integrated profit without integration
- Why worry about vertical integration?
 - two possible reasons
 - *price discrimination*
 - *vertical foreclosure*

Price discrimination

- Upstream firm selling to two downstream markets
 - different demands in the two markets

- ♦ the seller wants to price discriminate between these markets
- ♦ set $v_1 < v_2$
- ♦ but suppose that buyers can **arbitrage**
- ♦ then buyer 2 offers to buy from buyer 1 at a price v_a such that $v_1 < v_a < v_2$
- ♦ arbitrage prevents price discrimination
- ♦ if the seller integrates into market 1 arbitrage is prevented

Vertical foreclosure

- Vertically integrated firm refuses to supply other firms
 - so integration can eliminate competitors

- ♦ suppose that the seller is supplying three firms with an essential input
- ♦ the seller integrates with one buyer
- ♦ if the seller refuses to supply the other buyers they are driven out of business
- ♦ is this a sensible thing to do?

Vertical foreclosure 2

- Vertical foreclosure may reduce competition
 - offsets benefits of removing double marginalization
- But for this to work
 - foreclosure has to be a credible strategy for the merged firms
 - foreclosure must be *subgame perfect*
- Consider a model of foreclosure
 - Salinger (1988) with Cournot competition

Vertical foreclosure 3

- ◆ Suppose that there are some integrated upstream and downstream producers

- ◆ Profit of an integrated firm is:

$$\pi^I = (P^D - c_U - c_D)q_{Di}$$

- ◆ Profit of an independent upstream firm is:

$$\pi^U = (P^U - c_U)q_{Un}$$

- ◆ Profit of an independent downstream firm is:

$$\pi^D = (P^D - P^U - c_D)q_{Dn}$$

*The integrated firm will
not source on the independent
market*

*The integrated firm will
not sell on the independent
market*

Vertical foreclosure 4

- ◆ For the independent upstream firms to survive requires $P^U - c_U > 0$
- ◆ The downstream unit of an integrated firm obtains input at cost c_U
- ◆ Buying from an independent firm costs $P^U > c_U$

so the downstream divisions will not source externally

- ◆ Not selling upstream division of an integrated firm: it earns $P^U - c_U$
- ◆ Diverting output from the external market: this leads to a loss of $P^D - P^U - c_D$ per unit diverted

Profit from selling internally

Profit from selling externally

But this is true: so diverting output from the external market increases profits

$P^D - P^U - c_D > 0$ for independent downstream firms to survive

$P^D - c_U - c_D > P^U - c_U$ requires: $P^D - P^U - c_D > 0$

so the upstream divisions will not sell externally

- ◆ For the independent upstream firms to survive requires $P^U - c_U > 0$
- ◆ The downstream unit of an integrated firm obtains input at cost c_U
- ◆ Buying from an independent firm costs $P^U > c_U$

so the downstream divisions will not source externally

Profit from selling internally

**Profit from
selling
externally**

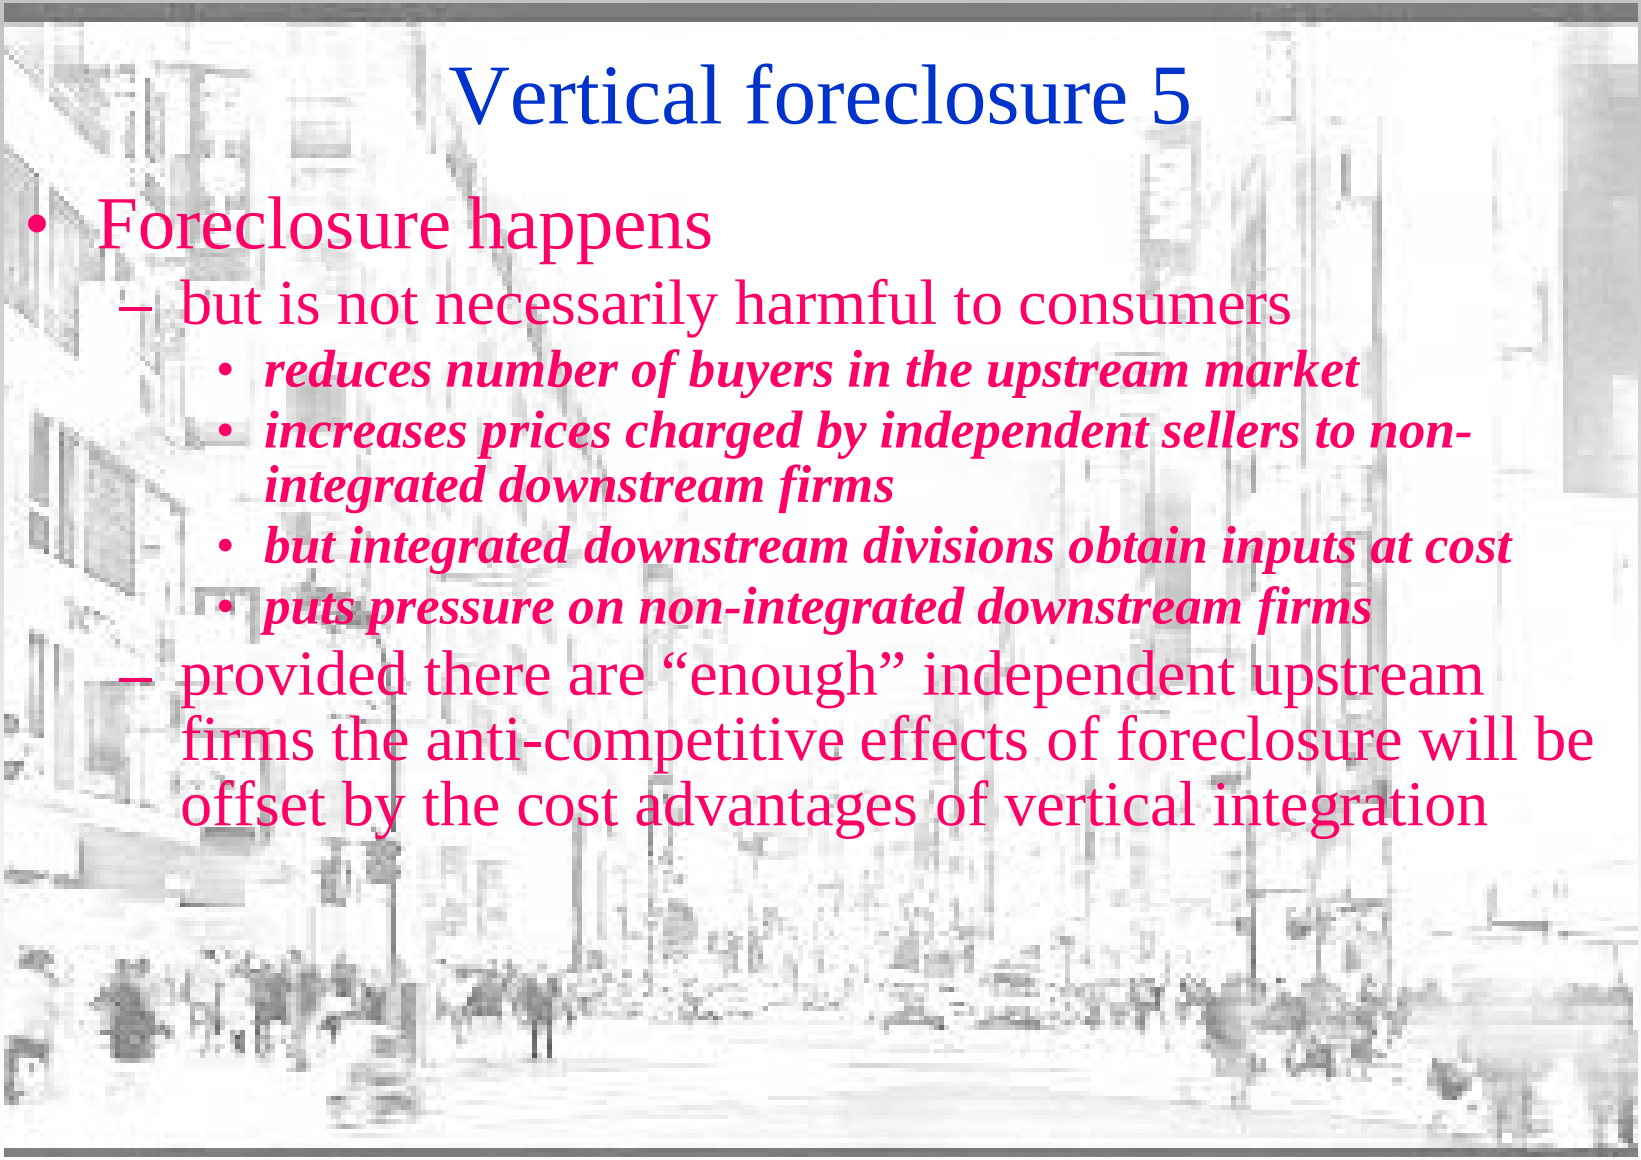

But this is true: so diverting output from the external market increases profits

◆ D	internally	Profit from selling	n: this lea
price un	ged: it ear		s unit div

$p^D - p^U - c > 0$ for independent downstream firms to survive

$$p^D - c_U - c_D > p^U - c_U \text{ requires: } p^D - p^U - c_D > 0$$

so the upstream divisions will not sell externally

Vertical foreclosure 5

- Foreclosure happens
 - but is not necessarily harmful to consumers
 - *reduces number of buyers in the upstream market*
 - *increases prices charged by independent sellers to non-integrated downstream firms*
 - *but integrated downstream divisions obtain inputs at cost*
 - *puts pressure on non-integrated downstream firms*
 - provided there are “enough” independent upstream firms the anti-competitive effects of foreclosure will be offset by the cost advantages of vertical integration

Vertical merger – reappraisal 2

- Recall the proposed GE-Honeywell merger
 - if this is the only merger then the merged firm gains and the non-merged firms lose
 - appears to be this that guided the EU Competition Directorate
 - but consumers benefit even in this scenario
 - and rivals have a clear strategic response: merge
 - so the EU must have believed that merger by rivals was not possible
 - Or would be strategically prevented by GE-Honeywell
 - and that if the integrated GE-Honeywell gains a monopoly position price will rise
 - Many believe that this was unlikely
- So the decision remains questionable

Conglomerate Mergers

- Bring under common control firms whose products are neither substitutes nor complements
 - results in a diversified firm
 - period from 1960s to early 1980s is when many were formed
- Is there a convincing rationale for this type of merger?
 - if not then probably an accident of history
 - gradually corrected by downsizing and focus on “core competence”
- Possible rationales:

Conglomerate mergers 2

- Economies of scope
 - but these generally derive from use of common inputs
 - so merged firms should be related in some respect
 - similar markets
 - similar technologies
 - data do not support this hypothesis

Conglomerate mergers 3

- Economize on transactions costs
 - take a specialized machine can produce two goods A and B
 - markets for A and B are concentrated
 - if machine is used to produce only A there is spare capacity
 - then owner may wish also to produce B – conglomeration
 - the owner could also lease use of the machine to a specialized B producer to avoid conglomeration
 - but this has problems
 - *negotiating and bargaining over the lease*
 - conglomeration avoids these problems
 - particularly important when the asset is knowledge intensive
 - so this motive is reasonable
 - but the assets are common to all the conglomerates products
 - not supported by the data

Conglomerate mergers 4

- Managerial motives
 - conglomeration suits interests of management but not shareholder
 - division of ownership and control of large public corporations
 - monitoring of management is far from perfect
 - so management can pursue its own agenda to some extent
 - suppose management compensation based on firm growth
 - easier to grow by acquisition than internally
 - horizontal merger may be blocked by regulators
 - so grow by conglomeration
 - conglomeration to reduce management risk
 - diversified firm has diversified risk
 - this diversifies the risk that management faces
- Seems to be supported by the evidence
