Canonical correlation analysis involves partition of variables into two vectors *x* and *y*. The aim is to find linear combinations $\alpha^T x$ and $\beta^T y$ that have the largest possible correlation.

Canonical Correlation Analysis

Let x be a p-variate random vector and let y be a q-variate random vector. The object in canonical correlation analysis is to find linear combinations

$$\boldsymbol{u}_{\boldsymbol{k}} = \boldsymbol{\alpha}_{\boldsymbol{k}}^{\mathsf{T}} \boldsymbol{x}$$

and

$$\mathbf{v}_{k} = \beta_{k}^{\mathsf{T}} \mathbf{y}$$

that maximizes the correlation $|corr(u_k, v_k)|$ between u_k and v_k subject to

$$var(u_k) = var(v_k) = 1,$$

and

$$corr(u_k, u_t) = 0, corr(v_k, v_t) = 0, t < k.$$

Whereas principal component analysis considers interrelationships within a set of variables, canonical correlation analysis considers relationships between two groups of variables.

Canonical Correlation Analysis, Regression Analysis

Canonical correlation analysis can be seen as an extension of multivariate regression analysis. However, note that in canonical correlation analysis there is no assumption of causal asymmetry - x and y are treated symmetrically!

Let
$$z = (x^T, y^T)^T$$
, and let

$$\mathit{cov}(z) = \Sigma = \left[egin{array}{cc} \Sigma_{11} & \Sigma_{12} \ \Sigma_{21} & \Sigma_{22} \end{array}
ight].$$

Define

$$M_1 = \Sigma_{11}^{-1} \Sigma_{12} \Sigma_{22}^{-1} \Sigma_{21},$$

and

$$M_2 = \Sigma_{22}^{-1} \Sigma_{21} \Sigma_{11}^{-1} \Sigma_{12}.$$

Now, the canonical vectors α_k are the eigenvectors of M_1 (α_k corresponds to the *k*th largest eigenvalue), the canonical vectors β_k are the eigenvectors of M_2 , and ρ_k^2 are the eigenvalues of the matrix M_1 (and of M_2 as well). The proof of this solution can be found from pages 283-284 of [1].

If the covariance matrices Σ_{11} and Σ_{22} are not full rank, similar results may be obtained using generalized inverses. One may also consider dimension reduction as a first step.

Canonical Correlation Analysis, Sample Version

Sample estimates $\hat{\alpha}_k$, $\hat{\beta}_k$ and $\hat{\rho}_k$ of α_k , β_k and ρ_k , respectively, are obtained by using sample covariance matrices calculated from the samples $x_1, x_2, ..., x_n, y_1, y_2, ..., y_n$ and $z_1, z_2, ..., z_n$.

Scoring and Predicting

Let *X* and *Y* denote the $n \times p$ and $n \times q$ data matrices for *n* individuals, and let $\hat{\alpha}_k$ and $\hat{\beta}_k$ denote the *k*th (sample) canonical vectors. Then the $n \times 1$ vectors

$$\eta_k = X \hat{\alpha}_k$$

and

$$\phi_{\mathbf{k}} = \mathbf{Y}\hat{\beta}_{\mathbf{k}}$$

▲ロト ▲周 ト ▲ ヨ ト ▲ ヨ ト つのの

denote the scores of the *n* individuals on the *k*th canonical correlation variables.

Lecturer: Pauliina Ilmonen Slides: Ilmonen/Kantala

Canonical Correlation

festing Independence

Scoring and Predicting

Nords of Warning

If the *x* and *y* variables are interpreted as the "predictor" and "predicted" variables, respectively, then the η_k score vector can be used to predict the ϕ_k score vector by using least square regression:

$$(\tilde{\phi_k})_i = \hat{\rho}_k((\eta_k)_i - \hat{\alpha}_k^T \bar{\mathbf{x}}) + \hat{\beta}_k^T \bar{\mathbf{y}}.$$

The canonical correlation $\hat{\rho}_k$ estimates the proportion of the variance of ϕ_k that is explained by the regression on *x*.

Some Words of Warning

- The procedure maximizes the correlation between the linear combination of variables — it can be more than difficult to interpret the results.
- Correlation does not automatically imply causality.
