## Exercise 5

1. Derive the probability that the insulation structure will pass the $15 / 2$ test ( 2 flashovers in 15 impulses). What is the probability with 125 kV test voltage when $50 \%$ breakdown voltage is 130 kV and standard deviation of breakdown is $3 \%$.
2. In order to determine an insulator's $50 \%$ breakdown voltage, a series of tests were conducted where voltage was increased steadily from 200 kV until breakdown occurred. The following breakdown values were obtained (in kV ): 478, 487, 503, 499, 481, 518, 530, 512, 495, 480, $471,535,505,507,491,498,506,521,482,493$. Determine the insulator's $50 \%$ breakdown voltage and its standard deviation using the probability sheet. Also, calculate the mean and experimental standard deviation using the measured data.
3. For the purchase of a 123 kV air insulating device, the impulse test voltage was set according to IEC as 450 kV . According to IEC, a 450 kV test voltage for an impulse voltage test correlates to $10 \%$ breakdown probability. Acceptance testing was conducted using up and down method. The test produces the following document ( $\mathrm{x}=$ breakdown, $\mathrm{o}=$ no breakdown):

Withstand strength is assumed to follow normal distribution when standard deviation $\sigma=3 \%$. Did the device pass the test?

Hint: Respective breakdown voltage $\mathrm{U}_{\mathrm{p}}$ for breakdown probability p can be estimated using the mean and standard deviation according to the following table.

$$
U_{p}=U_{50}-k \sigma
$$

| $\mathrm{p} / \%$ | 50 | 15,9 | 10 | 2,3 | 0,13 |
| :--- | :--- | :--- | :--- | :--- | :--- |
| k | 0 | 1 | 1,3 | 2,0 | 3,0 |

The table shows $(0,1)$ normal distribution function:

$$
\Phi(\lambda)=\frac{1}{\sqrt{2 \pi}} \int_{-\lambda}^{+\lambda} e^{-\frac{\lambda^{2}}{2}} d \lambda
$$

| $\lambda$ | $\Phi(\lambda)$ | $\lambda$ | $\Phi$ ( $\mathrm{\lambda}^{\text {. }}$ | $\lambda$ | $\Phi(\lambda)$ | $\lambda$ | $\Phi(\lambda)$ | $\lambda$ | $\Phi(\lambda)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

$\Phi(\lambda) \hat{=}$ probability that $(0,1)$ distributed random value falls within $-\lambda \ldots . . \lambda$.
$(\mu, \sigma)$ normal and $(0,1)$ normal random value is correlated as:

$$
\lambda=\frac{x-\mu}{\sigma}
$$

where $x \hat{=}(\mu, \sigma)$ distribution random value.
