

# ELEC-E8119 Reinforcement Learning Planning in Discrete Space Introduction to Optimal Control

Ville Kyrki 17.9.2018

### Today

- Traditional (discrete) planning
- How to plan with complete knowledge?
- Connection to optimal control

# **Learning goals**

- Formulate discrete planning problems.
- Use value iteration as a way to solve them.
- Explain relationship between discrete planning and optimal control.

• What are: state space, initial state, goal states set, action space, state transition (dynamics) function?

# Planning as graph search – General search algorithm

- Keep track of visited states (dead and alive).
  - Pick an alive state and visit one of the unvisited states (reachable and not dead).
  - Only difference between algorithms how to choose the state to visit.

Propose algorithms!

### **Search strategies**

- Are all search strategies good?
- Systematic graph search
  - All states will be visited (for finite graphs)
  - If solution exists, it will be found in finite time (for infinite graphs)

## **Shortest paths**

- Associate each edge of graph with nonnegative cost
- Cost of plan is the sum of costs

Shortest path from S to B?

# Dijkstra's algorithm

- Idea:
  - Keep track of "cost-to-come", i.e. accumulated minimum cost to reach a particular state
  - Expand state with minimum cost-to-come
  - Update "cost-to-come" estimates until optimum is reached.
- Computational complexity O(|V| log |V| + |E|)
- Exercise: Solve shortest paths from S in the previous graph using Dijkstra.
- A\* extension of Dijkstra with heuristic lower bound.

# **Optimal planning (fixed-length plans)**

Like feasible planning, plus

cost functional

 $L(\tau_{K}) = \sum_{k=1}^{K} l(x_{k}, u_{k}) + l_{F}(x_{K+1}) \qquad \tau_{K} = (u_{1}, \dots, u_{K})$  $l_{F}(x) = \frac{0, x \in X_{G}}{\infty, x \notin X_{G}}$ 

• Goal:  $min_{\tau}L(\tau)$ 

# **Solving optimal planning**

- Principle of Optimality (Bellman, 1957): An optimal policy has the property that whatever the initial state and initial decision are, the remaining decisions must constitute an optimal policy with regard to the state resulting from the first decision.
- Value-function:
  - cost-to-go  $G_k^*(x_k)$

$$G_{k}^{*}(x_{k}) = min_{u_{k},...,u_{K}} \left\{ \sum_{i=k}^{K} l(x_{i}, u_{i}) + l_{F}(x_{F}) \right\}$$

#### **Backward value iteration**

• Assume we know  $G_{k+1}^*(x)$ how to compute  $G_k^*(x_k)$ ?

$$G_{k}^{*}(x_{k}) = min_{u_{k},...,u_{K}} \left\{ \sum_{i=k}^{K} l(x_{i}, u_{i}) + l_{F}(x_{F}) \right\}$$

$$G_{k}^{*}(x_{k}) = \min_{u_{k}} \left\{ l(x_{k}, u_{k}) + G_{k+1}^{*}(x_{k+1}) \right\} \qquad G_{K+1}^{*}(x) = l_{F}(x)$$
$$= \min_{u_{k}} \left\{ l(x_{k}, u_{k}) + G_{k+1}^{*}(f(x_{k}, u_{k})) \right\}$$

Aalto University School of Electrical Engineering "Try all actions for this step and choose best."

# Value iteration, unknown length plans

 Iterating recursion until value function stationary: optimal cost plans have been found from all states that can reach a goal state

$$G^{*}(x) = min_{u} \left[ l(x, u) + G^{*}(f(x, u)) \right]$$

**Bellman equation** 

- Using  $G_{,}^{*}$  optimal actions can be found from  $u^{*} = argmin_{u \in U(x)} \{ l(x, u) + G^{*}(f(x, u)) \}$
- Complexity  $O(K|X||U|) = O(|X|^2|U|)$

Aalto University School of Electrical Engineering

Why? Compare to Dijkstra!

#### Exercise

• Use backward value iteration for

$$x_I = S$$
$$X_G = \{B\}$$

# Link to linear quadratic regulator (LQR)

- Plant  $x_{k+1} = A x_k + B u_k$
- Minimize  $J(u_{1,...,u_{K}}) = \sum_{k=1}^{K-1} (x_{k}^{T}Qx_{k} + u_{k}^{T}Ru_{k}) + x_{K}^{T}Q_{f}x_{K}$
- Value function

$$V_{t}^{*}(x_{t}) = min_{u_{t},...,u_{K}} \sum_{k=t}^{K-1} \left( x_{k}^{T} Q x_{k} + u_{k}^{T} R u_{k} \right) + x_{K}^{T} Q_{f} x_{K}$$

• Bellman / Hamilton-Jacobi equation  $V_t^*(x_t) = x_t^T Q x_t + min_{u_t} \left( u_t^T R u_t + V_{t+1}^* (A x_t + B u_t) \right)$ 

Solution in the readings for this lecture (there's minor error, though).

Aalto University School of Electrical Engineering

Compare to 
$$G^*(x) = min_u \{l(x, u) + G^*(f(x, u))\}$$

# Find the error(s)

$$V_{t}^{*}(x_{t}) = x_{t}^{T} Q x_{t} + min_{u_{t}} (u_{t}^{T} R u_{t} + V_{t+1}^{*} (A x_{t} + B u_{t}))$$
$$V_{t+1}^{*}(x) = x^{T} P_{t+1} x$$

$$0 = \frac{\partial}{\partial u} u_t^T R u_t + (A x_t + b u_t)^T P_{t+1} (A x_t + b u_t)$$
  
= 2 u<sup>T</sup> R + 2 x<sup>T</sup> A<sup>T</sup> P\_{t+1} B + u<sup>T</sup> B<sup>T</sup> P\_{t+1} B

# Find the error(s)

$$V_{t}^{*}(x_{t}) = x_{t}^{T} Q x_{t} + min_{u_{t}} (u_{t}^{T} R u_{t} + V_{t+1}^{*} (A x_{t} + B u_{t}))$$
$$V_{t+1}^{*}(x) = x^{T} P_{t+1} x$$

$$0 = \frac{\partial}{\partial u} u_t^T R u_t + (A x_t + b u_t)^T P_{t+1} (A x_t + b u_t)$$
$$= 2 u^T R + 2 x^T A^T P_{t+1} B + u^T B^T P_{t+1} B$$

Now solve for u!

#### **Summary**

- Feasible planning can be understood as search.
- Optimal planning can be solved by dynamic programming using a recursive formulation of value function.
- Optimal control of linear systems with quadratic costs can be done using Bellman equation similar to discrete planning.
