

ECON-C4100 - Capstone: Econometrics I

Lecture 6: Multiple regression #1: estimation

Otto Toivanen

Learning outcomes

- At the end of this lecture, you
 - 1 understand what how multivariate regression differs from univariate regression.
 - 2 understand how and why to carry out a multivariate regression analysis.
 - 3 appreciate the assumptions made in multivariate regression analysis.
 - 4 are aware of the most common pitfalls in regression analysis.

Starting point:

$$Y = f(X_1, X_2, \dots, X_k, u)$$

- Outcome variable of interest a function of several variables.
- Observables and unobservables.
- One or more hypotheses (needed)?

Income, age and gender

- ① Is income affected by age?
 - ② Do women and men of same age earn differently?
- Let's study these using the open access FLEED data of Statistics Finland.
 - These data can be downloaded from the Statistics Finland [web page](#).
 - We will use the year 15 (= 2010) cross section data.

Univariate regression

$$Y = f(X, u) = \beta_0 + \beta_1 X + U$$

$$\mathbb{E}[Y|X = x] = \beta_0 + \beta_1 x$$

Multivariate/multiple regression

$$Y = f(X_1, X_2, u) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + u$$

$$E[Y|\mathbf{X} = \mathbf{x}] = \beta_0 + \beta_1 x_1 + \beta_2 x_2$$

More structure - linear

$$Y = \beta_0 + \beta_1 X_1 + \beta_2 X_2$$

- This is the so called **population regression line (populaatio regressio)**.
- $Y =$ **dependent variable (vastemuuttuja)** or **endogenous variable**.
- $X_k =$ **independent variable k** (selittävä muuttuja) or **exogenous variable k** or *regressor k* .
- $\beta_0, \beta_1, \beta_2$: **parameters of the model**.

Are all Xs born equal?

- Depends...
- Treatment variable = the one of primary interest.
- Control variable(s) = affect(s) Y but we are not (so much) interested in this/these.
- Why include variables that we are not interested in?

What type of control variables matter, how & why?

① $cov(X_1, X_2) = 0$

② $cov(X_1, X_2) \neq 0$

- Key is whether the treatment variable and control variable are correlated or not.

What type of control variables matter, how & why?

- Why is this key? Recall

$$\hat{\beta}_1 = \beta_1 + \rho_{xu} \frac{\sigma_u}{\sigma_x}. \quad (1)$$

Rewrite

$$u = \beta_2 X_2 + v \quad (2)$$

What type of control variables matter, how & why?

Assume

$$\text{cov}(\mathbf{X}, v) = \mathbf{0}$$

Then

$$\hat{\beta}_1 = \beta_1 + \beta_2 \rho_{X_1 X_2} \times \frac{\sigma_{X_2}}{\sigma_{X_1}} \quad (3)$$

Make sure you know how to derive equation (3).

What type of control variables matter, how & why?

If the X s are correlated, then the bias in β_1 depends on

- 1 the impact of X_2 on Y (β_2).
- 2 the correlation between the X s ($\rho_{X_1X_2}$).
- 3 how much variance X_2 has relative to X_1 ($\frac{\sigma_{X_2}}{\sigma_{X_1}}$).

What type of control variables matter, how & why?

- So are we home if $\text{cov}(X_1, X_2) = 0$?
- Yes and no.
- If $\text{cov}(X_1, X_2) = 0$ then $\hat{\beta}_1 = \beta_1$
- However, adding X_2 decreases the standard error / increases the precision of $\hat{\beta}_1$.

What type of control variables matter, how & why?

- A two-variable model (App 6.2. in S&W).
- 2 explanatory variables and homosced. errors, $\rho_{X_1, X_2} = 0$. Then

$$\sigma_{\hat{\beta}_1}^2 = \frac{1}{n} \frac{\sigma_u^2}{\sigma_{X_1}^2}$$

which is the variance of $\hat{\beta}_1$.

- Adding X_2 necessarily decreases σ_u^2 (make sure you understand why this is the case).

Income modeled as function of age and gender?

- Let's look at the following model:

$$Income_i = \beta_0 + \beta_{AgeMV} Age_i + \beta_{GMV} G_i + u_{MV_i}$$

Where

Age_i = age in years.

G_i = dummy for gender.

MV stands for **M**ultivariate.

Should we suspect that age affects income?

- Experience increases with age.
- In a cross-section such as ours, younger people typically better educated than older (conditional on not being too young).
- Physical condition and mental agility start to decrease relatively early.

Should we suspect that gender affects income?

- Segregation of job market a well known phenomenon.
- Women bear a larger share of household work and stay longer at home after getting a child.
- Educational levels and fields differ by gender.

Some conditional descriptive statistics

```
. tabstat income age if year == 15, stat(mean sd p50) by(gender)
```

Summary statistics: mean, sd, p50
by categories of: gender

gender	income	age
0	25478.2	41.5928
	18894.06	16.10072
	24000	42
1	21053.65	42.15153
	14852.83	16.48018
	20000	43
Total	23296.67	41.86563
	17163.61	16.28821
	21000	43

Are age and gender correlated in our data?

```
. pwcorr age gender if year == 15, sig
```

	age	gender
age	1.0000	
gender	0.0171 0.1755	1.0000

Mean income conditional on age and gender

Stata code

```
1 bysort age gender: egen income_m_age_g = mean(income)
2 bysort age gender: gen win_age_g_ind = _n
3 twoway scatter income_m_age_g age if gender == 1 & win_age_g_ind == 1 || ///
4     scatter income_m_age_g age if gender == 0 & win_age_g_ind == 1, ///
5     legend(lab (1 "female") lab (2 "male")) ///
6     graphregion(fcolor(white)) ///
7     ytitle("income") ///
8     title("Mean income | age & gender")
9 graph export "mean_income_age_gender.png", replace
```

Mean income conditional on age and gender

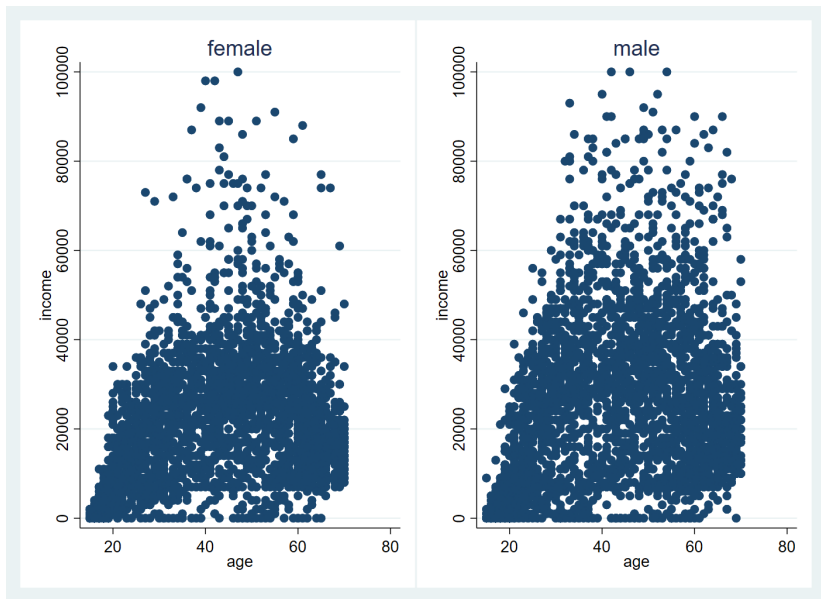

Income-age scatter by gender

Stata code

```
1 scatter income age if gender == 0 & year == 15, ///
2   graphregion(fcolor(white)) ///
3   title("male") ///
4   saving(income_age_male, replace)
5 scatter income age if gender == 1 & year == 15, ///
6   graphregion(fcolor(white)) ///
7   title("female") ///
8   saving(income_age_female, replace)
9 gr combine income_age_female.gph income_age_male.gph
10 graph export "income_age_gender.png", replace
```

Income-age scatter by gender

How to get β_0 , β_1 & β_2 : OLS

$$\min_{\beta_0, \beta_1, \beta_2} \sum_{i=1}^n [Y_i - (\beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i})]^2 \quad (4)$$

$$\min_{\beta} (\mathbf{Y} - \mathbf{X}\beta)' (\mathbf{Y} - \mathbf{X}\beta) \quad (5)$$

How to get β_0 , β_1 & β_2 : OLS

$$\hat{\beta}_1 = \frac{\sum x_2^2 \sum x_2 y - \sum x_1 x_2 \sum x_1 y}{\sum x_1^2 \sum x_2^2 - (\sum x_1 x_2)^2}$$

$$\hat{\beta} = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\mathbf{Y})$$

- Note: now not using matrix algebra leads to very cumbersome mathematics; with matrix algebra, the solution stays the same as with univariate regression.
- The expression for $\hat{\beta}_2$ is symmetric with that of $\hat{\beta}_1$.
- Finally, $\hat{\beta}_0 = \bar{Y} - \hat{\beta}_1 \bar{X}_1 - \hat{\beta}_2 \bar{X}_2$.

Let's compare univariate regressions to multivariate regression

$$Income = \beta_{0AgeUV} + \beta_{AgeUV} Age + u_{AgeUV} \quad (6)$$

$$Income = \beta_{0GUV} + \beta_{GUV} G + u_{GUV} \quad (7)$$

$$Income = \beta_0 + \beta_{AgeMV} Age + \beta_{GMV} G + u_{MV} \quad (8)$$

Regression commands

Stata code

```
1  regr income age      if year == 15
2  eststo income_age
3  regr income gender   if year == 15
4  eststo income_gender
5  esttab income_age income_gender using "regr_income_table.tex", ///
6      label se scalars(r2 F) ///
7      title(Univariate income regressions \label{tab1}) replace
8  regr income age gender if year == 15
9  eststo income_age_gender
10 testparm age gender
11 test age = gender
12 pwcorr age gender if e(sample)
13 sum age gender if e(sample)
14 esttab income_age income_gender income_age_gender using "regr_income_table2.tex", ///
15     label se scalars(r2 F) ///
16     title(Income regressions \label{tab1}) replace
```

Issues?

- ① How do the individual coefficients compare to univariate results?
- ② What explains the difference(s)?
- ③ What about statistical significance of individual coefficients?
- ④ What about several / all coefficients?
- ⑤ What about R^2 ?

Issues?

- ⑥ What is the interpretation of individual coefficients?
- ⑦ (under what assumptions) Does OLS work?
- ⑧ How to choose which explanatory variables to include / exclude?
- ⑨ What if the world is more complicated than linear?
- ⑩ What all can go wrong, and how would I know / find out?

Q1 & Q2 multivariate vs. univariate?

- 1 How do the individual coefficients compare to univariate results?
- 2 What explains the difference(s)?

Q1 & Q2 multivariate vs. univariate?

- Compare the *Age* coefficient in the univariate to that in the multivariate regression.
- What can you conclude? Recall

$$\hat{\beta}_{AgeUV} = \beta_{AgeMV} + \beta_{GMV} \rho_{Age,G} \times \frac{\sigma_G}{\sigma_{Age}}$$

Q1 & Q2 multivariate vs. univariate?

- Plug numbers from the previous slide into the bias formula:

$$\begin{aligned} \text{Bias}_{\beta_{\text{ageUV}}} &= \beta_{\text{GMV}} \rho_{\text{Age,G}} \times \frac{\sigma_G}{\sigma_{\text{Age}}} \\ &= -4545.02 \times 0.0126 \times \frac{0.500}{15.987} = -1.791 \end{aligned}$$

- Compare to

$$\beta_{\text{AgeUV}} - \beta_{\text{AgeMV}} = 296.754 - 298.548 = -1.794$$

- Do the same for gender.
- What can you conclude?

Q1 & Q2 multivariate vs. univariate?

- Multivariate regression allows the researcher to
 - ① control for observable variables and thereby either remove (omitted variable) bias and/or increase efficiency.
 - ② test several hypotheses simultaneously.
 - ③ (as we will see), enrich the main hypotheses to allow for heterogeneous effects.

Q3 & Q4 statistical significance, individual coefficients

- 3 What about statistical significance of individual coefficients?
- 4 What about the statistical significance of several / all coefficients?

Q3 & Q4 statistical significance, individual coefficients

- Can we reject the null that
 - ① $\beta_0 = 0$,
 - ② $\beta_{Age} = 0$,
 - ③ $\beta_G = 0$?

Q3 & Q4 statistical significance, individual coefficients

```
. regr income age gender          if year == 15
```

Source	SS	df	MS	Number of obs	=	5,973

_cons	12819.2	634.6356	20.20	0.000	11575.09	14063.32

Q3 & Q4 statistical significance, individual coefficients

- Are $\beta_0, \beta_{Age}, \beta_g$ all = 0?
- F - test (and others) for the *joint significance*.
- Cannot do this by looking at individual (t-) tests.
- Reason: two or more random variables \rightarrow need their joint distribution.

Q3 & Q4 statistical significance, individual coefficients

- F test (under homosk.). For illustration only.

$$F = \frac{(SSR_{restricted} - SSR_{unrestricted})/q}{SSR_{unrestricted}/(n - k_{restricted} - 1)}$$
$$= \frac{(R^2_{unrestricted} - R^2_{restricted})/q}{(1 - R^2_{unrestricted})/(n - k_{restricted} - 1)}$$

- Modern software calculate the heterosk. robust F-test.

Q3 & Q4 statistical significance, individual coefficients

```
. regr income age gender          if year == 15
```

Source	SS	df	MS	Number of obs	=	5,973
Model	1.6524e+11	2	8.2622e+10	F(2, 5970)	=	309.43

_cons	12819.2	634.6356	20.20	0.000	11575.09	14063.32

Q3 & Q4 statistical significance, individual coefficients

- What about $\beta_{Age} = \beta_G = 0$?
- In other words, Null hypothesis is that a subset of parameters are zero.
- Modern software allow this.

Q3 & Q4 statistical significance, individual coefficients

```
. testparm age gender  
  
( 1) age = 0  
( 2) gender = 0  
  
F( 2, 5970) = 309.43  
Prob > F = 0.0000
```

Q3 & Q4 statistical significance, individual coefficients

- What about $\beta_{Age} = \beta_G$?
- Need either a direct test modern software allow this (easily).
- Or a trick (add and subtract).

Q3 & Q4 statistical significance, individual coefficients

```
. test age = gender  
  
( 1) age - gender = 0  
  
F( 1, 5970) = 130.92  
Prob > F = 0.0000
```

Q3 & Q4 statistical significance, individual coefficients

- With multivariate regression:
 - ① Important to check the regression diagnostic statistics (F-test) (more on this to follow).
 - ② Rich possibilities to test hypotheses that involve multiple parameters.

Q5 What about R^2 ?

$$R^2 = \frac{ESS}{TSS} = 1 - \frac{SSR}{TSS}$$

- R^2 increases (almost) surely as you add explanatory variables.
- Adjusted R^2 corrects for this:

$$adjR^2 = 1 - \frac{n-1}{n-k-1} \frac{SSR}{TSS} = \frac{s_{\hat{u}}^2}{s_Y^2}$$

- n = number of obs; k = number of expl. variables.
- Adjusted R^2 always lower than R^2 .

Q5 What about R^2 ?

```
. regress income age gender          if year == 15
```

Source	SS	df	MS	Number of obs	=	5,973
Model	1.6524e+11	2	8.2622e+10	F(2, 5970)	=	309.43
Residual	1.5940e+12	5,970	267009188	Prob > F	=	0.0000
				R-squared	=	0.0939
				Adj R-squared	=	0.0936
Total	1.7593e+12	5,972	294589468	Root MSE	=	16340

income	Coef.	Std. Err.	t	P> t	[95% Conf. Interval]	
age	298.5478	13.22762	22.57	0.000	272.6169	324.4787
gender	-4545.022	422.9347	-10.75	0.000	-5374.127	-3715.917
_cons	12819.2	634.6356	20.20	0.000	11575.09	14063.32

Q5 What about R^2 ?

- High R^2 / an increases in R^2 says nothing about causality.
- High R^2 does not mean your model does not suffer from omitted variable bias.
- High R^2 does not mean you have the right set of explanatory variables.
- High R^2 tells nothing about the economic significance of your results.
- High R^2 means that factors outside your model (= the stuff going into the error term) play a relatively speaking smaller role in the process that determines the value of Y .
- But, as we saw from the F-test formula, (changes in) R^2 are indicative and a certain level of R^2 is needed to reject the Null that all your model parameters are insignificant.
