School of Chemical Engineering

# Overview

We combined the notions on dynamic systems and simulation with the notions on nonlinear programming, to formulate a general **discrete-time optimal control** problem

- We understood and treated them as special forms of nonlinear programs

$$\begin{aligned} \min_{\substack{x_0, x_1, \dots, x_K \\ u_0, u_1, \dots, u_{K-1}}} \quad & E(x_K) + \sum_{k=0}^{K-1} L(x_k, u_k) \\ \text{subject to} \quad & x_{k+1} - f(x_k, u_k | \theta_x) = 0, \quad k = 0, 1, \dots, K-1 \\ & h(x_k, u_k) \leq 0, \quad k = 0, 1, \dots, K-1 \\ & r(x_0, x_K) \leq 0 \end{aligned}$$

---

In general, the system dynamics are defined in continuous time

- ↪ The control inputs are continuous functions of time

We are interested in the continuous-time formulation

- We discuss more precisely the discretisation

# Formulation

## Continuous-time optimal control

# Formulation

The simplest form of continuous-time optimal control lets all functions be continuous

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

That is, the optimisation is over state and control trajectories,  $x(0 \rightsquigarrow T)$  and  $u(0 \rightsquigarrow T)$

## Formulation (cont.)

Formulation

Numerics

The state are a continuous and differentiable function of time over the interval  $[0, T]$

Similarly, also the controls are function of time over  $[0, T]$

~> Though, they can be rough or jumpy fuctions

## Formulation (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} \underbrace{E(x(T))}_{\text{Mayer term}} + \underbrace{\int_0^T L(x(t), u(t)) dt}_{\text{Lagrange term}}$$

Bolza objective function

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

We constrain the initial value of the state to be  $x_0$ , by explicitly setting  $x(0) = x_0$

Moreover, we constrain the state to satisfy the continuous-time dynamics in  $[0, T]$

$$\dot{x}(t) - f(x(t), u(t)) = 0, \quad t \in [0, T]$$

When the initial state  $x(0)$  is fixed and the trajectory of the controls  $u(t)$  are known in  $[0, T]$ , the dynamic constraint will determine the trajectory of the state  $x(t)$  in  $[0, T]$

## Formulation (cont.)

Formulation

Numerics

$$\dot{x}(t) - f(x(t), u(t)) = 0, \quad t \in [0, T]$$

In discrete-time, we have expressed the dynamic constraint as a vector of constraints

$$\underbrace{\begin{bmatrix} x_1 - f(x_0, u_0) \\ x_2 - f(x_1, u_1) \\ \vdots \\ x_{k+1} - f(x_k, u_k) \\ \vdots \\ x_{K-1} - f(x_{K-2}, u_{K-2}) \\ x_K - f(x_{K-1}, u_{K-1}) \end{bmatrix}}_{K \times N_x}$$

In continuous-time, the dynamic constraint is understood as an infinitely long vector

## Formulation (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} \underbrace{E(x(T)) + \int_0^T L(x(t), u(t)) dt}_{\text{Bolza objective function}}$$

Mayer term
Lagrange term

subject to

$\dot{x}(t) - f(x(t), u(t)) = 0,$	$t \in [0, T]$	(Dynamics)
$h(x(t), u(t)) \leq 0,$	$t \in [0, T]$	(Path constraints)
$x_0 - x(0) = 0$	$(t = 0)$	(Initial value)
$r(x(T)) \leq 0$	$(t = T)$	Terminal constraint

We constrain trajectories along the path, by explicitly setting an inequality constraint

## Formulation (cont.)

Formulation

Numerics

$$h(x(t), u(t)) \leq 0, \quad t \in [0, T]$$

In discrete-time, we have expressed the path constraint as a vector of constraints

$$\begin{bmatrix} h(x_0, u_0) \\ h(x_1, u_1) \\ \vdots \\ h(x_k, u_k) \\ \vdots \\ h(x_K, u_K) \end{bmatrix}$$

In continuous-time, the path constraint is understood as an infinitely long vector

## Formulation (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} \underbrace{E(x(T))}_{\text{Mayer term}} + \underbrace{\int_0^T L(x(t), u(t)) dt}_{\text{Lagrange term}}$$

Bolza objective function

subject to

$\dot{x}(t) - f(x(t), u(t)) = 0,$	$t \in [0, T]$	(Dynamics)
$h(x(t), u(t)) \leq 0,$	$t \in [0, T]$	(Path constraints)
$x_0 - x(0) = 0$	$(t = 0)$	(Initial value)
$r(x(T)) \leq 0$	$(t = T)$	Terminal constraint

A terminal constraint is expressed as inequality constraint on the terminal state  $x(T)$

# Numerics

## Continuous-time optimal control

# Overview of numerical approaches

There exist three main classes of approaches to solve continuous-time optimal control

- **State-space methods** are based on the Bellman's **principle of optimality**
  - The **Hamilton-Jacobi-Bellman** equation, HJB
  - (Continuous-time dynamic programming)
- **Indirect methods** are based on the Pontryagin's **minimum principle**
  - First-optimize, then discretise
- **Direct methods** are based on transcriptions as **nonlinear programs**
  - First-discretise, then optimise

## Direct methods | Single-shooting

Formulation

Numerics

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

subject to	$\dot{x}(t) - f(x(t), u(t)) = 0,$	$t \in [0, T]$	(Dynamics)
	$h(x(t), u(t)) \leq 0,$	$t \in [0, T]$	(Path constraints)
	$x_0 - x(0) = 0$	$(t = 0)$	(Initial value)
	$r(x(T)) \leq 0$	$(t = T)$	Terminal constraint

---

The general idea of single shooting methods is common to all the shooting methods

- Use an embedded integrator of the differential model
- To eliminate the continuous-time dynamics

## Direct methods | Single-shooting

Formulation

Numerics

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

## First-discretise, then optimise

- Define a fixed time-grid for  $[0, T]$

$$0 = t_0 < t_1 < \dots < t_{K-1} < t_K = T$$

The time-intervals do not need to be necessarily equally spaced, though this is common

## Direct methods | Single-shooting (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

subject to

$\dot{x}(t) - f(x(t), u(t)) = 0,$	$t \in [0, T]$	(Dynamics)
$h(x(t), u(t)) \leq 0,$	$t \in [0, T]$	(Path constraints)
$x_0 - x(0) = 0$	$(t = 0)$	(Initial value)
$r(x(T)) \leq 0$	$(t = T)$	Terminal constraint

---

## First-discretise, then optimise

- Define a fixed time-grid for  $[0, T]$ 

$$0 = t_0 < t_1 < \dots < t_{K-1} < t_K = T$$
- Discretise the controls  $u(t)$

$$u(t \in [t_k, t_{k+1}]) = u_k$$

The control trajectory  $u(t)$  is commonly parameterised by piecewise constant functions

- Other parameterisations are possible (other piecewise polynomials)

## Direct methods | Single-shooting (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

## First-discretise, then optimise

- Define a fixed time-grid for  $[0, T]$ 

$$0 = t_0 < t_1 < \dots < t_{K-1} < t_K = T$$
- Discretise the controls  $u(t)$ 

$$u(t \in [t_k, t_{k+1}]) = u_k$$
- Treat the states  $x(t)$  as function of discretised controls  $\{u_k\}$  and  $x_0$

## Direct methods | Single-shooting (cont.)

- Define a fixed time-grid for  $[0, T]$ 

$$0 = t_0 < t_1 < \dots < t_{K-1} < t_K = T$$
- Discretise the controls  $u(t)$ 

$$u(t \in [t_k, t_{k+1}]) = u_k$$
- Treat the states  $x(t)$  as function of discretised controls  $\{u_k\}$  and  $x_0$

Consider the time  $t \in [t_k, t_{k+1}]$ , the zero-order hold control active on the interval is  $u_k$

We denote the state trajectory over the short interval  $[t_k, t_{k+1}]$  as the **solution map**

$$\tilde{x}_k(t|x_k, u_k), \quad t \in [t_k, t_{k+1}]$$

The final value of the short trajectory is the output of the **transition function**

$$\tilde{x}_k(t_{k+1}|x_k, u_k) = f_{\Delta t}(x_k, u_k)$$

## Direct methods | Single-shooting (cont.)

$$\begin{aligned}
 & \min_{\substack{x_0, x_1, \dots, x_K \\ u_0, u_1, \dots, u_{K-1}}} E(x_K) + \sum_{k=0}^{K-1} L_k(x_k, u_k) \\
 & \text{subject to } x_{k+1} - f_{\Delta t}(x_k, u_k | \theta_x) = 0, \quad k = 0, 1, \dots, K-1 \\
 & \quad h(x_k, u_k) \leq 0, \quad k = 0, 1, \dots, K-1 \\
 & \quad r(x_0, x_K) \leq 0
 \end{aligned}$$

Discretising the controls transcribes the infinite dimensional problem into a finite one

Single-shooting regards the states  $x_k$  as dependent variables obtained by integration

- From the initial state  $x_0$ , under the sequence of controls  $\{u_k\}$

$$\begin{aligned}
 x_0 &= \underbrace{x_0}_{\bar{x}_0(x_0)} \\
 x_1 &= \underbrace{f_{\Delta t}(x_0, u_0)}_{\bar{x}_1(x_0, u_0)} \\
 x_2 &= f_{\Delta t}(x_1, u_1) \\
 &= \underbrace{f_{\Delta t}(f_{\Delta t}(x_0, u_0), u_1)}_{\bar{x}_2(x_0, u_0, u_1)} \\
 \dots &= \dots
 \end{aligned}$$

## Direct methods | Single-shooting (cont.)

Formulation

Numerics

$$\begin{aligned} \min_{u_0, u_1, \dots, u_{K-1}} \quad & E(\bar{x}_K(x_0, u_0, u_1, \dots, u_{K-1})) + \sum_{k=0}^{K-1} L(\bar{x}_k(x_0, u_0, u_1, \dots, u_{K-1}), u_k) \\ \text{subject to} \quad & h(\bar{x}_k(x_0, u_0, u_1, \dots, u_{K-1}), u_k) \leq 0, \quad k = 0, 1, \dots, K-1 \\ & r(x_0, \bar{x}_N(x_0, u_0, u_1, \dots, u_{K-1})) = 0 \end{aligned}$$

Simulation and optimisation are solved sequentially, the approach is the sequential one

The only decision variable in the nonlinear program is the collection of control vectors

- The decision variable influences all of the problem functions

$$\underbrace{u_0, u_1, \dots, u_{K-1}}_{K \times N_u}$$

## Direct methods | Single-shooting (cont.)

The nonlinear program is dense, any generic solver can be used for the task

The Lagrangian function  $\mathcal{L}(w, \lambda, \mu)$

$$\begin{aligned}\mathcal{L}(w, \lambda, \mu) \\ = f(w) + \lambda^T g(w) + \mu^T h(w)\end{aligned}$$

The Hessian of the Lagrangian

$$\nabla_w^2 \mathcal{L}(w, \lambda, \mu)$$

In general, there is no structure in  $\nabla_w^2 \mathcal{L}(w, \lambda, \mu)$

$$\frac{\partial^2 \mathcal{L}(w, \lambda, \mu)}{\partial w_i \partial w_k} \neq 0$$

## Direct methods | Single-shooting (cont.)

Single shooting solution using simulation based on a order-4 Runge-Kutta integrator

The state trajectory can be computed during the iterations of the optimisation scheme

- The model equations are satisfied by definition

# Direct methods | Single-shooting (cont.)

# Direct methods | Single-shooting (cont.)

Formulation

Numerics

The **forward integrator map** of the system dynamics is formally defined as a function

$$\begin{aligned} f_{\text{int}} : \mathcal{R}^{N_x + (K \times N_u)} \times \mathcal{R} &\rightarrow \mathcal{R}^{N_x} \\ &: (x_0, u_0, u_1, \dots, u_{K-1}, t) \mapsto x(t) \end{aligned}$$

Function  $f_{\text{int}}$  propagates continuous dynamics, it may get highly nonlinear for large  $T$

## Example

$$\begin{aligned}\dot{x}(t) &= 10(y(t) - x(t)) \\ \dot{y}(t) &= x(t)(u(t) - z(t)) - y(t) \\ \dot{z}(t) &= x(t)y(t) - 3z(t)\end{aligned}$$

From some fixed initial condition  $(x_0, y_0, z_0)$  and constant control  $u(t)$

System's states  $x(t)$  as a function of the controls  $u(t) = \text{const}$ , at simulation time  $t$

Time  $t = 0.45$  [s]

Time  $t = 0.65$  [s]

Time  $t = 0.85$  [s]

Time  $t = 1.05$  [s]

Time  $t = 1.25$  [s]

Time  $t = 1.45$  [s]

## Direct methods | Single-shooting (cont.)

For short integration times, the relationship between states and controls is close to linear and as the becomes highly nonlinear with the duration of the simulation time

## Direct methods | Multiple-shooting

Formulation

Numerics

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

The general idea of multiple shooting methods is common to all the shooting methods

- Use an embedded integrator of the differential model
- To eliminate the continuous-time dynamics

Yet, the integration of the dynamics over a long period of time can be counterproductive

↔ Restrict the integration to relatively shorter intervals

## Direct methods | Multiple-shooting (cont.)

Formulation

Numerics

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

## First-discretise, then optimise

- Define a fixed time-grid for  $[0, T]$

$$0 = t_0 < t_1 < \dots < t_{K-1} < t_K = T$$

The time-intervals do not need to be necessarily equally spaced, though this is common

## Direct methods | Multiple-shooting (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

## First-discretise, then optimise

- Define a fixed time-grid for  $[0, T]$ 

$$0 = t_0 < t_1 < \dots < t_{K-1} < t_K = T$$
- Discretise the controls  $u(t)$

$$u(t \in [t_k, t_{k+1})) = u_k$$

The control trajectory  $u(t)$  is commonly parameterised by piecewise constant functions

- Other parameterisations are possible (other piecewise polynomials)

## Direct methods | Multiple-shooting (cont.)

$$\min_{\substack{x(0 \rightsquigarrow T) \\ u(0 \rightsquigarrow T)}} E(x(T)) + \int_0^T L(x(t), u(t)) dt$$

$$\begin{aligned} \text{subject to } \dot{x}(t) - f(x(t), u(t)) &= 0, & t \in [0, T] & \quad \text{(Dynamics)} \\ h(x(t), u(t)) &\leq 0, & t \in [0, T] & \quad \text{(Path constraints)} \\ x_0 - x(0) &= 0 & (t = 0) & \quad \text{(Initial value)} \\ r(x(T)) &\leq 0 & (t = T) & \quad \text{Terminal constraint} \end{aligned}$$

Treat the states  $x(t)$  as function of discretised controls  $u_k$ , starting from a given  $x_k$

## Direct methods | Multiple-shooting (cont.)

The integration of the dynamics is performed over the much shorter interval  $[t_k, t_{k+1}]$

- The forward integrator is only mildly nonlinear

$$x_{k+1} = f_{\Delta t}(x_k, u_k | \theta_x)$$

The states  $x_k$  used in the integration become decision variables of the optimisation

$$\begin{aligned} \min_{\substack{x_0, x_1, \dots, x_K \\ u_0, u_1, \dots, u_{K-1}}} & E(x_K) + \sum_{k=0}^{K-1} L(x_k, u_k) \\ \text{subject to} & x_{k+1} - f_{\Delta t}(x_k, u_k | \theta_x) = 0, \quad k = 0, 1, \dots, K-1 \\ & h(x_k, u_k) \leq 0, \quad k = 0, 1, \dots, K-1 \\ & r(x_0, x_N) = 0 \end{aligned}$$

## Direct methods | Multiple-shooting (cont.)

The integration over the interval  $[t_k, t_{k+1}]$  is meaningful if the shooting gap is closed

$$x_{k+1} - f_{\Delta t}(x_k, u_k | \theta_x) = 0$$

To ensure continuity, the shooting gaps become equality constraints of the optimisation

$$\min_{\substack{x_0, x_1, \dots, x_K \\ u_0, u_1, \dots, u_{K-1}}} E(x_K) + \sum_{k=0}^{K-1} L(x_k, u_k)$$

$$\text{subject to } x_{k+1} - f_{\Delta t}(x_k, u_k | \theta_x) = 0, \quad k = 0, 1, \dots, K-1$$

$$h(x_k, u_k) \leq 0, \quad k = 0, 1, \dots, K-1$$

$$r(x_0, x_N) = 0$$

## Direct methods | Multiple-shooting (cont.)

Multiple shooting solution using simulation based on a order-4 Runge-Kutta integrator

Because the continuity conditions hold, the short-interval simulations join at time nodes

- The model equations satisfied only once the nonlinear program has converged

# Direct methods | Multiple-shooting (cont.)

Formulation

Numerics

# Direct methods | Multiple-shooting (cont.)

Formulation

Numerics

## Direct methods | Multiple-shooting (cont.)

The nonlinear program is sparse, structure-exploiting solvers should be used

The Lagrangian function  $\mathcal{L}(w, \lambda, \mu)$

$$\begin{aligned} \mathcal{L}(w, \lambda, \mu) \\ = f(w) + \lambda^T g(w) + \mu^T h(w) \end{aligned}$$

The Hessian of the Lagrangian

$$\nabla_w^2 \mathcal{L}(w, \lambda, \mu)$$

The Hessian of the Lagrangian is block-diagonal, with small symmetric blocks

- All the other second derivatives are zero

The block-diagonality property of the Hessian is extremely favourable

- ↪ Hessian approximations
- ↪ QP subproblems
