General presentation of acoustic radiation force

- Langevin radiation pressure, P_{Lan} , is defined as the energy density (time average over one cycle, sinusoidal wave) $P_{\text{Lan}} = \langle E \rangle_T = \hat{p}^2/2\rho_0 c^2$
- The radiation force is a **vector quantity** and can be defined from the energy density as follows:

$$F = d_r < E >_T S$$

where d_r is a *drag coefficient* vector containing two perpendicular unit vectors p and q in a 2D simplification.

Drag coefficient

• In 2D the drag coefficient can be written as

Perfect reflection, no absorption

• E.g. wave meets a fluid-air interface at normal angle

$$d_{r} = \frac{p}{S} \left(\underbrace{\Pi_{a}}_{=0} + \Pi_{s} - \Delta S \sum_{i} \gamma_{i} \cos \theta_{i} \right) - \frac{q}{S} \left(\Delta S \sum_{i} \gamma_{i} \sin \theta_{i} \right)$$
$$= -\Pi_{s}$$
$$= 0$$
$$= 2\Pi_{s}$$

 $d_r = |\boldsymbol{d}_r| = 2\Pi_s = 2 \text{ (in p - direction)} \Rightarrow F = 2 < E >_T S$

Rayleigh scatterer

• Scatterer smaller than the wavelength:

Perfect absorption, no reflection

• E.g. wave meets an oily target

$$d_{r} = \frac{p}{S} \left(\underbrace{\prod_{a} + \prod_{s} - \Delta S}_{i} \sum_{i} \gamma_{i} \cos \theta_{i} \right) - \frac{q}{S} \left(\Delta S \sum_{i} \gamma_{i} \sin \theta_{i} \right)$$
$$= 0$$
$$= 0$$
$$= 0$$

 $d_r = |\boldsymbol{d}_r| = \Pi_a = 1 \text{ (in p - direction)} \Rightarrow F = \langle E \rangle_T S$

Radiation force –based drug release of nanoparticles from lipid micro-bubbles

Fluorescent Nanoparticles (20 or 400 nm) loaded on a lipid-shelle micro-bubble

Fig. 3. Nanobead distribution on the surface of the vehicles. Vehicles were created as described in Materials and methods. A sample of the vehicle solution was observed on a 100× water immersion objective. The fluorescence within the image is yellow-green fluorescence emitted by the nanobeads bound to the microbubble surface. The scale bar corresponds to 5 μ m in length.

Step 1: 1.3-s radiation force pulse at 3 MHz,
150 kPa PNP
Step 2: 5-cycle fragmentation pulse at 1.5 MHz
and 1.1 MPa PNP

Radiation force –based drug release of agent from lipid micro-bubbles

Radiation force –induced thrombolysis

Blood clots in latex tubes

Goal: to improve tissue plasminogen activator (tPA)mediated thrombolysis

Ultrasonic "pinball": SAW drive-in

Sketch of the SAW-driven passive dispenser and time sequence of the dispensing process as explained in the text. In (a), the IDT on the left is activated to push the reservoir droplet towards the hydrophilic anchor. In (b), the hydrophilic anchor is wetted by the reservoir. In (c), switching off the SAW retracts the reservoir droplet leaving a small droplet at the anchor site. In (d), a second SAW is used to push the dispensed droplet toward a container anchor (larger gray area to the upper right).

Powder transportation

Transportation of Al2O3 particles (~50µm size particles). Translation speed 60-180 mm/s (30 fps)
